Earthquake design spectrum in Chinese Design Code

List of seismic codes

1. Earthquake load in GBJ11-89

A design acceleration response spectrum is obtained as follows:

\[ \alpha_{\text{max}} : \text{the maximum acceleration (G) determined from seismic intensity zone IV - IX} \]

\[ T_g : \text{the period (sec) determined from site category I - IV} \]

(a) Frequently occurred earthquakes

<table>
<thead>
<tr>
<th>Intensity</th>
<th>VI</th>
<th>VII</th>
<th>VIII</th>
<th>IX</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \alpha_{\text{max}} )</td>
<td>0.04</td>
<td>0.08</td>
<td>0.15</td>
<td>0.32</td>
</tr>
</tbody>
</table>

(b) Rare earthquakes

<table>
<thead>
<tr>
<th>Intensity</th>
<th>VII</th>
<th>VIII</th>
<th>IX</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \alpha_{\text{max}} )</td>
<td>0.50</td>
<td>0.90</td>
<td>1.40</td>
</tr>
</tbody>
</table>

Figure 1. A design acceleration response spectrum (GBJ11-89)
Earthquake loads along the height of the building

\[ F_{E_k} = a_1 G_{x_1} \]

\[ F_i = \frac{G_i H_i}{\sum_{j=1}^{n} G_j H_j} (1 - \delta_i) \quad (i = 1, 2 \cdots n) \]

\[ \Delta F_s = \delta_s F_{E_k} \]

2. Earthquake load in GB50011-2001

A design acceleration response spectrum is obtained as follows:

\[ \alpha = \begin{cases} 
(0.45 + \eta_2 - 0.45) \alpha_{\text{max}} / 0.1 & \text{if } T \leq 0.1 \\
\frac{T}{T_g} \eta_1 \alpha_{\text{max}} & \text{if } 0.1 < T \leq T_g \\
\frac{T}{T_g} \eta_2 \alpha_{\text{max}} & \text{if } T_g < T \leq 5T_g \\
[\eta_1 (0.2 - \eta_1 (T - 5T_g))] \alpha_{\text{max}} & \text{if } 5T_g \leq T \leq 6.0 
\end{cases} \]

where,

\( \eta_1, \eta_2, \gamma \): coefficients determined from damping ratio, \( \zeta \),

\[ \eta_1 = \frac{0.02 + (0.05 - \zeta)}{8}, \eta_1 \geq 0 \]

\[ \eta_2 = 1 + \frac{0.05 - \zeta}{0.06 + 1.75 \zeta}, \eta_2 \geq 0.55 \]

\[ \gamma = 0.9 + \frac{0.05 - \zeta}{0.5 + 5 \zeta} \]
\( \alpha_{\text{max}} \): the maximum acceleration (G) determined from seismic intensity zone IV - IX

<table>

Earthquake loads along the height of the building

\[
\begin{align*}
F_{Es} &= a_1 G_{e1} \\
F_i &= \frac{G_i H_i}{\sum_{j=1}^{n} G_j H_j} F_{Ek} (1 - \delta_i) \quad (i = 1, \ 2 \cdots n) \\
\Delta F_s &= \delta_s F_{Es}
\end{align*}
\]
Seismic Intensity Zone

Figure 3. Seismic Intensity Zoning Map in China
(provided by Dr. Okawa, BRI)

The affected area of the Sichuan Earthquake on May 12, 2008 locates in Zone VII.
3. Example

Figure 4 compares the design acceleration response spectra for different seismic intensity zones IV-IX where the factor $T_g$ is assumed to be 0.4sec.

Also, the dotted line in the Figure shows the design acceleration response spectrum of the Japanese seismic design code for soil type 1.

The difference between the design spectra among seismic intensity zones is very large; the spectrum of zone IX is 5 times larger than that of zone IV.

The design spectrum of zone IX exceeds Japanese one in the range of short natural period.

The affected area of the Sichuan Earthquake on May 12, 2008 locates in Zone VII. Therefore, the earthquake load of the new buildings in that area corresponds to the half of the earthquake load of Japanese ones. Also it corresponds to the maximum ground acceleration 150-200gal.
